

React Components

- Functional Components
- Class Components

React Components

In React, a component is a reusable piece of the user interface. Think of it like a block. You can build complex structures by combining multiple blocks together. Components can be simple like a button or more complex like an entire form.

Types of Components

- Function Components
- Class Components

Function Components

Function components are the simpler and more commonly used type of component. They are written as JavaScript functions.

Example : A simple button component

```
// Importing React
import React from 'react';

// Defining a function component
function MyButton() {
  return (
    <button>Click Me!</button>
  );
}

// Exporting the component to use in other files
export default MyButton;
```

Button Component

In this example, `MyButton` is a function that returns a button element with the text "Click Me!".

Class Components

Class components are a bit more complex and were more common before React Hooks were introduced. They are written as ES6 classes.

Example : A simple button component as a class

```
// Importing React and Component
import React, { Component } from 'react';

// Defining a class component
class MyButton extends Component {
  render() {
    return (
      <button>Click Me!</button>
    );
  }
}

// Exporting the component to use in other files
export default MyButton;
```

In this example, `MyButton` is a class that extends `React.Component` and has a `render` method that returns a button element.

Using Components

To use a component in your application, you import it and include it in your **JSX code**.

Example : **Using the MyButton component**

```
// Importing React and the MyButton component
import React from 'react';
import MyButton from './MyButton';

// Defining the App component
function App() {
  return (
    <div>
      <h1>Hello, React!</h1>
      <MyButton />
    </div>
  );
}

// Exporting the App component
export default App;
```

In this example, the **App component** renders an **h1** element and the **MyButton component**. When you run this application, you'll see "Hello, React!" and a button that says "Click Me!".
