

Default Export & Named Export

In **React** , there are two main ways to export and import modules: **default exports** and **named exports**.

Lets understand both of them with simple explanation and examples

Default Export

A default export is used to export a single value from a module. This can be a function, class, object, or primitive value. When you import a default export, you can give it any name you like.

Let's understand it, with simple example →

File: `MyComponent.js`

```
// This is a default export
function MyComponent() {
  return <h1>Hello, World!</h1>;
}

export default MyComponent;
```

File: `App.js`

```
import MyComponent from './MyComponent';

function App() {
  return (
    <div>
      <MyComponent />
    </div>
  );
}

export default App;
```

In the example above, `MyComponent` is exported as the default export from `MyComponent.js`. When importing it in `App.js`, you can use any name you like or use the same name

Named Export

A named export allows you to export **multiple values** from a module. When you import named exports, you must use the **exact names** of the exports **within curly braces**.

Let's understand it, with simple example →

File: MyComponent.js

```
// These are named exports
export function Header() {
  return <h1>Header Component</h1>;
}

export function Footer() {
  return <h1>Footer Component</h1>;
}
```

File: App.js

```
import { Header, Footer } from './MyComponents';

function App() {
  return (
    <div>
      <Header />
      <Footer />
    </div>
  );
}

export default App;
```

In the example above, `Header` and `Footer` are exported as `named exports` from `MyComponents.js`. When importing them in `App.js`, you must use the exact names within `curly braces`.

You can also combine **default** and **named exports** in the same module.

File: **MyComponent.js**

```
// Default export
function Main() {
  return <h1>Main Component</h1>;
}

// Named exports
export function Header() {
  return <h1>Header Component</h1>;
}

export function Footer() {
  return <h1>Footer Component</h1>;
}

export default Main;
```

File: **App.js**

```
import Main, { Header, Footer } from
'./MyComponents';

function App() {
  return (
    <div>
      <Header />
      <Main />
      <Footer />
    </div>
  );
}

export default App;
```

Summary

Default Export: Use for a single export per module. Import *without curly braces* and can be *renamed* on import.

Named Export: Use for *multiple exports* from a module. Import *using curly braces* with exact names.

Understanding these concepts will help you organize your code better and make your React components easier to manage and reuse.
